

1. What problem/use case did they have?

Delivery Hero had a problem with **employees getting locked out of their accounts**.

- Employees had to contact the **IT team** to recover access.
- IT had to verify the employee's identity.
- IT then had to restore access in **Okta and Google Workspace**.
- Around **800 account-recovery requests** were received every month.
- Each request took approximately **35 minutes**.
- This meant employees were unable to work while waiting for their accounts to be restored.

Main problem:

A repetitive, manual IT process was consuming a lot of time for both employees and the IT team.

2. Where and why did they implement n8n?

They implemented **n8n as the automation layer connecting multiple systems** involved in the account-recovery process.

The key systems were:

- **Okta** – identity and account access
- **Jira** – IT/service request management
- **Google Workspace** – employee account access
- **n8n** – automation/orchestration

The main reason for using n8n was to **remove IT as a bottleneck**.

Instead of:

Employee → IT → Identity verification → IT approval → Restore account

They changed it to:

Employee → Manager approval → n8n → Okta/Jira/Google → Account restored

So, the manager became responsible for approving the recovery, while n8n handled the technical steps automatically.

3. How was the n8n workflow implemented?

The workflow essentially worked like this:

Employee gets locked out

Employee requests account recovery

Direct Manager receives approval request

Manager verifies and approves

n8n workflow is triggered

Automated API calls

Okta Jira Google

Restore Update Restore
access request access

Employee regains

access

The important point is that **n8n orchestrated the different applications through API calls.**

Instead of an IT employee manually performing the same steps in different systems, n8n automatically triggered those actions once the manager approved the recovery.

4. How did n8n help in the real-world scenario?

The biggest impact was **reducing the time employees remained locked out.**

Before automation

IT handled recovery

Manual IT activities

~35 minutes average

~800 requests/month

After automation

Manager approves recovery

Automated workflow

~20 minutes average

Requests handled automatically

IT spent significant time on repetitive work IT bottleneck reduced

Results

The average recovery time dropped:

35 minutes → 20 minutes

That's a **15-minute reduction per request.**

With around 800 requests per month:

800 × 15 minutes = 12,000 minutes

= 200 hours saved per month.

So, n8n didn't just automate a technical task—it **reduced employee downtime and freed the IT team from repetitive account-recovery work.**

What did Delivery Hero do next?

The success of this workflow encouraged Delivery Hero to look for **other repetitive IT processes that could be automated using n8n**, including:

- **Account offboarding**
- **Software license assignments**
- Other manual IT processes

Simple takeaway

Delivery Hero used n8n to connect Okta, Jira, and Google Workspace and automate account recovery after manager approval. This reduced employee lockout time from 35 to 20 minutes and saved about 200 hours of employee downtime every month.

This is a good example of n8n being used as an **automation/orchestration platform**, rather than employees manually working across multiple applications.
